How do you measure deployment of it space?

The most common measure of deployment of IT space is the IT cabinet. There are other types of devices such as storage arrays and mainframes that are not cabinets, but they can, in most cases, easily be described as roughly equivalent to one or more cabinets in size.

How much power is allowed per cabinet?

The design target average power per cabinet is 5 kW. The peak power allowed in any cabinet is 12.5 kW as long as the pod power does not exceed 50 kW for all 12 cabinets combined. The total indoor space required by this design is 25,320 ft² (2,352 m²).

How much power does a data center cabinet use?

Almost every data center has some variation of power among cabinets. It is common to find cabinets operating from 50 watts (a network switch with patch panels) up to 30 kW (fully loaded high performance blade servers). This represents a range of 60 to 1in power consumption.

What is a data center cabinet specification?

The specification is hierarchical and modular, so that different rooms and zones can have different density requirements. The specification comprehends that IT cabinets within data centers have different power requirements, and that these requirements may not be well-defined in advance.
