The battery scientists put several charging windows to the test, namely the 0%-25%, 0%-60%, 0%-80%, 0%-100%, and 75%-100% ranges at two ambient temperature points.

In this article, we will discuss the Tesla battery degradation chart, what is considered normal degradation, and answer some common questions about battery degradation in Tesla vehicles.

If you simply store an LFP battery at 50% charge in 55 °C, it will only last 1 year. The optimal charge level at 25 °C is 90%, which translates to 33 years of life.

LFP Teslas are newer, so there's not a whole lot of info about real-world battery degradation for them. For NCM Teslas, it's normal for them to lose ...

Tesla's LFP batteries facing an unexpected challenge! Dive into the mystery of degradation--what's causing the dip in performance? The answers await.

Tesla cars are known for their long range, providing hundreds of miles on a single full charge--but how does the battery hold up after years of use? To find out, we've analysed real-life ...

How long does a Tesla battery last in real-world use? Learn about Tesla battery lifespan, degradation rates, NCA vs. LFP chemistry, warranty coverage, and why 15-20 years is realistic for ...

If your car doesn't have an LFP battery then generally stick to 80% or less for daily charging but feel free to use 100% if you are going on a trip that will challenge your range.

Tesla recently shared a chart presenting the average battery capacity retention per distance traveled of the Model 3 and Model Y cars with Long Range battery packs, and it's good ...

Contrary to the widespread belief that LFP (Lithium Iron Phosphate) batteries last longer, the data shows NCA

Tesla lfp battery degradation chart

or NCM batteries have lower degradation rates compared to LFP batteries. Of ...

LFP Teslas are newer, so there's not a whole lot of info about real-world battery degradation for them. For NCM Teslas, it's normal for them to lose roughly 5% in the first year, then ...
